

How to assemble an asymmetric capacitor?

Before assembling an asymmetric capacitor, the positive and negative electrode materials need to be tested separately in a three-electrode configuration with a counter electrode (usually high surface area platinum wire/sheet) and a reference electrode (usually saturated calomel or Ag/AgCl) in an aqueous electrolyte.

How is specific capacitance calculated?

The specific capacitance is equivalent to the amount of charge stored per unit gram of the active material and is denoted by Farad per gram ( $Fg^{-1}$ ). The  $C_{sp}$  of any material is usually calculated from two electrochemical measurements, which are cyclic voltammetry (CV) and galvanostatic charge-discharge (GCD) profiles. a.

What is the difference between symmetric and asymmetric supercapacitors?

The obtained capacitance in symmetric supercapacitors mainly originates from the double layer formation. While in asymmetric supercapacitors, both the Faradaic reactions (pseudo-capacitance) and the electric double layer participate in the total charge.

What is the maximum capacitance of a fabricated asymmetric device?

The fabricated asymmetric device showed excellent electrochemical performance in the potential window of 0.0 to 2.2V, exhibiting a maximum capacitance of  $0.67 Fcm^{-3}$  at  $5 mV s^{-1}$  scan rate.

How to calculate asymmetric supercapacitor with high electrochemical performance?

In order to obtain an asymmetric supercapacitor with high electrochemical performance, the charge balance between the two electrodes should follow the relationship  $q_+ = q_-$ . The  $q$  is the charge stored by electrode, which can be calculated by the equation:

How do you calculate charge and mass balance of a symmetric supercapacitor?

The charge and mass balance equation of a symmetric supercapacitor The amount of charge accumulated in a supercapacitor electrode is related to the  $C_{sp}$  is given by the following equation [24,25] (16.11)  $Q = C_{sp, material} \cdot m_{active material} \cdot D V$  Thus, (16.12)  $m_{active material} = \frac{Q}{C_{sp, material} \cdot D V}$

It exhibits a prominent specific capacitance of  $1575 F g^{-1}$  at  $1 A g^{-1}$ , and the as-assembled asymmetric supercapacitor device exhibits remarkable energy density of  $75.36 Wh kg^{-1}$  at a power density of  $399 W kg^{-1}$  and outstanding cycling stability with only 18.36% capacitance loss over 5000 cycles.
