

Why do tantalum capacitors fail?

When connected to a power supply a high initial current will be present at the capacitor (can be in the order of 10 Ampere and more). This is due to the very low internal series resistance of the tantalums. Albeit this is a short event it causes heat and stress within the capacitor and may result in a failure.

How can a capacitor reduce stress?

A better way to relieve stress from these components, without any knowledge of the circuit itself would be to use a capacitor with a higher voltage rating. This will translate to a larger, more expensive component but it will stress less. Another way would be to get a "quality" capacitor, from a brand name supplier.

Can I use a ceramic capacitor at 10uF?

At 10uF you can successfully use a ceramic capacitor (perhaps it will be a bit bigger) and avoid the ignition issue. You may have to use 15uF or 22uF to actually get 10uF at the working voltage, especially if you choose a relatively small capacitor that is rated for close to 5V.

Should I de-Rate my capacitor?

If it'd be possible (given the size constraints that you have), I'd de-rate your capacitor (use a higher voltage rating than required) and also put a smaller ceramic capacitor in parallel. These are more tolerant to short high-voltage spikes and will help reduce the stress on the electrolytic.

Does the canor aspect innate talent stack?

The Canor Aspect's innate Talent has a similar effect and they can stack. Prerequisites: 35 Charisma The head equipment "Investigator's Hat" and "Tophat" have this Talent. Off Your Game [Common Talent, Charisma]- You now slow Taunted enemies when you hit them. Prerequisites: Taunt (Charisma Mantra), 90 Charisma

Why do capacitors fail?

They may also fail due to high surge current, e.g. if the capacitor is initially empty and then connected to a power supply with high peak current capability. When connected to a power supply a high initial current will be present at the capacitor (can be in the order of 10 Ampere and more).

If it is indeed a capacitor-start motor (not PSC; Permanent Split Capacitor), then the start capacitor is

energized only during starting. Once the motor has reached about 1/2-2/3 speed, the start capacitor and start winding are de-energized, usually by a centrifugal switch inside the motor.

If it was a "wet" capacitor with a gel / liquid electrolyte, that was likely either ethylene glycol (aka "anti-freeze") or boric acid (think Borax laundry soap). If it was a solid capacitor, the equivalent of an electrolyte was another film of manganese dioxide (MnO<sub>2</sub>). Wet caps usually pop, but not smoke.

That explains it :-D You can't measure capacitors while they are attached to something. That's how electronics work. In order to check capacity you have to desolder it. When you touched the leads the capacitor discharged immediately ...

I have a 1040STF that has had a lot of work done: RD-50A PSU, Marpet 4MB RAM upgrade, Gotek, drive A/B toggle switch It seemed fine, until today I noticed burning of the bulk capacitor's (C149 / 4700uF / 16V) positive side. Voltage over the capacitor is a neat 4,95V.

The failure rate of Tantalum capacitors will decrease with time and not increase as with other electrolytic capacitors and other electronic components. IMO tantalum are fine for this application. I wouldn't be concerned about age unless you have some very special requirements.
