Flywheel Energy Storage System (FESS) operating at high angular velocities have the potential to be an energy dense, long life storage device. Effective energy dense storage will be required for the colonization in extraterrestrial applications with intermittent power sources.

The primary goal in flywheel design is to maximise specific energy storage, guided by the stress limits that the materials can withstand. Employing high-strength materials or composites allows for a reduction in mass while permitting higher rotational speeds, which in turn, enhances the specific energy storage capacity [73].

Among these options, the flywheel energy storage is the best choice for storing tens to hundreds of kilojoules of energy for mobile machinery. The flywheel is an old means of energy storage and smoothing out power variations [63]. However, bulky structures caused by low strength materials and excessive energy losses caused by traditional ...

In this paper, based on a 400kW homopolar inductor machine/generator for flywheel energy storage system, the design method is proposed, and the no-load back electromotive force is calculated by magnetic circuit method according to its design parameters. Finally, the experiments of the prototype are carried out, and the results calculated by ...

In this paper, a simple three-phase bridge circuit is adopted to realize the energy feedback for BLDCM driven flywheel energy storage system (FESS) to avoid the additional control or drive circuit problems. The energy feedback is a key to realize the energy exchange, which is affected significantly by the PWM modulation method. The energy ...

The flywheel energy storage system (FESS) has excellent power capacity and high conversion efficiency. ... Finally, experiments are performed to test the charging/discharging ability, and the results show that an excellent control current could enhance the charging/discharging efficiency so the stable DC link voltage could be outputted at the ...

The difference between the loading energy and motor energy is the energy supplied by FESS, which can be denoted as [36]:
$$E_{\text{Flywheel}} = \frac{1}{2} J (\omega_{\text{max}}^2 - \omega_{\text{min}}^2) = E_{\text{Load}} - E_{\text{Motor}}$$
 where E_{Flywheel} denotes the energy provided by the flywheel, E_{Load} denotes the energy required by the load, E_{Motor} denotes the energy output of the motor, J denotes ...
