How does a solid state battery work?

In a solid state battery, the principle is the same but you remove the separator and liquid electrolyte, and instead you have a solid electrolyte between the two electrodes. A solid electrolyte can enable a lithium metal anode which has ten times the theoretical capacity of a graphite anode, doubling the cell energy density.

What are the components of a solid state battery?

It includes: Basic structure: Solid-state batteries consist of three main components: an anode (negative electrode), a cathode (positive electrode), and a solid electrolyte that separates them. Anode and Cathode materials: The anode is often made from lithium metal in solid-state batteries, which contributes to their higher energy density.

What is a solid state battery?

The liquid electrolyte gets substituted by a solid electrolyte which is why these batteries are referred as solid state batteries. Many people get confused that solid state batteries are totally different type of batteries than the existing lithium ion batteries. That is not the case.

What is the basic working principle of solid state batteries?

Pranav: The basic working principle of Solid state batteries is same as the conventional lithium ion batteries. In conventional Lithium ion batteries, lithium in the cathode splits into Lithium ion and electron. The electron travel through the outer network while the Lithium ion swims through the liquid electrolyte to reach the anode.

What are the fabrication techniques for solid-state batteries (SSBs)?

Other methods, such as plasma technology and atomic layer deposition (ALD), are also being explored as potential fabrication techniques for solid-state batteries owing to their attractive features (Fig. 1). Fig. 1. Schematic diagram of the fabrication techniques for solid state batteries (SSBs) and their features.

Which cathode material should a solid state battery be made of?

But with solid state batteries it's not so clear what the cathode materials will be composed of. If you use a material without cobalt, nickel or manganese such as lithium iron phosphate (LFP) cathode, this is ethically better but with EV as you want a high voltage cathode for increased energy density, this would need to be nickel-based.
